Questions on Assignment One

Recap: Summary of the Taxonomy of Communication Networks

Recap: Circuit Switching vs. Packet Switching

	circuit switching	packet switching	
resource usage	use a single partition bandwidth	use whole link bandwidth	
reservation/setup	need reservation (setup delay)	no reservation	
resource contention	busy signal (session loss)	congestion (long delay and packet losses)	
charging	time	packet	
header	no per-pkt header	per packet header	
fast path processing	fast	per packet processing	

Recap: Queueing Theory

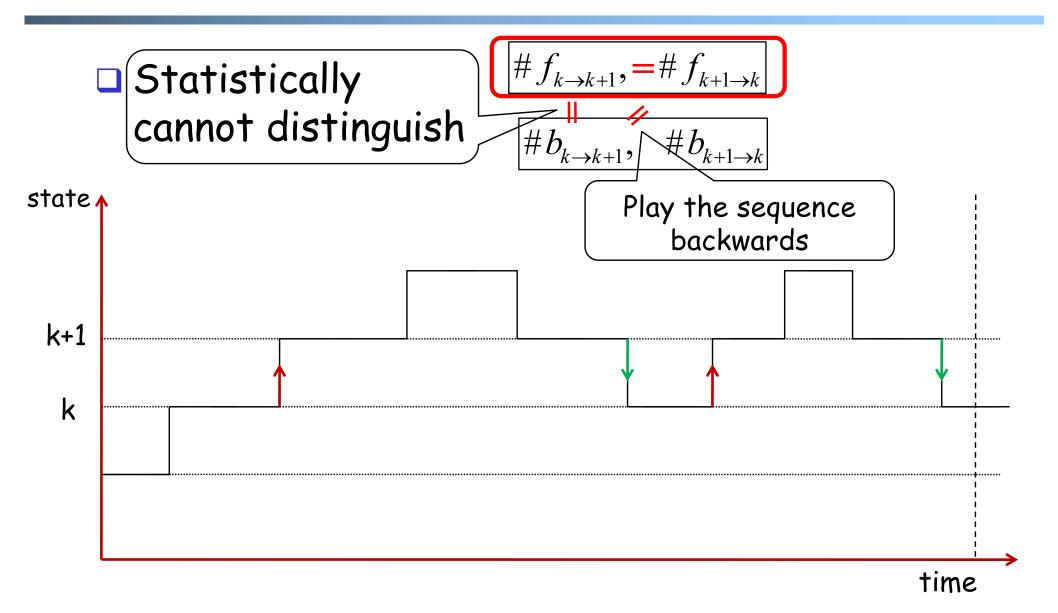

- Model system state
- □ Introduce state transition diagram
- Focus on equilibrium: state trend neither growing nor shrinking

Recap: Queueing Theory Analysis of Circuit-Switching

system state: # of busy lines

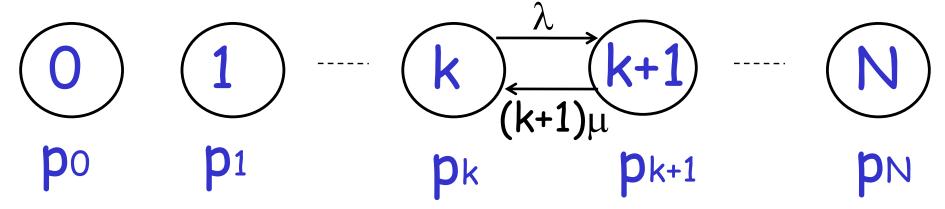

Equilibrium = Time Reversibility [Frank Kelly]

Recap: Queueing Theory Analysis of Circuit-Switching

system state: # of busy lines

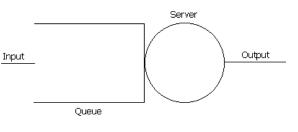

at equilibrium (time reversibility) in one unit time: $\#(\text{transitions k} \rightarrow \text{k+1}) = \#(\text{transitions k+1} \rightarrow \text{k})$

$$p_k \lambda = p_{k+1}(k+1)\mu$$

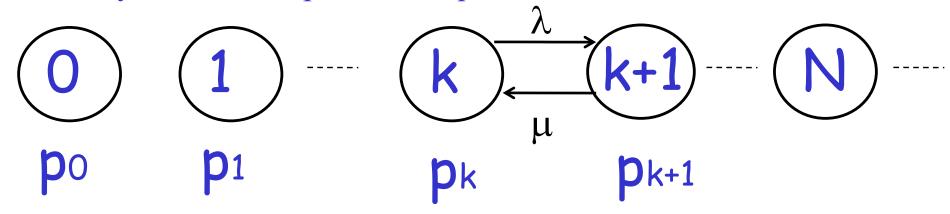

$$p_{k+1} = \frac{1}{k+1} \frac{\lambda}{\mu} p_k = \frac{1}{(k+1)!} \left(\frac{\lambda}{\mu}\right)^{k+1} p_0$$

$$p_0 = \frac{1}{1 + \frac{1}{1!} \frac{\lambda}{\mu} + \frac{1}{2!} \left(\frac{\lambda}{\mu}\right)^2 + \dots + \frac{1}{N!} \left(\frac{\lambda}{\mu}\right)^N}$$

Recap: Queueing Theory Analysis of Packet Switching

system state: #packets in queue

at equilibrium (time reversibility) in one unit time:

#(transitions $k \rightarrow k+1$) = #(transitions $k+1 \rightarrow k$)

$$p_k \lambda = p_{k+1} \mu$$

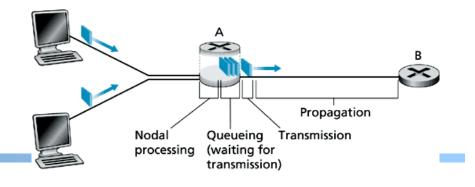

$$\sum_{k=0}^{\infty} p_k = 1$$

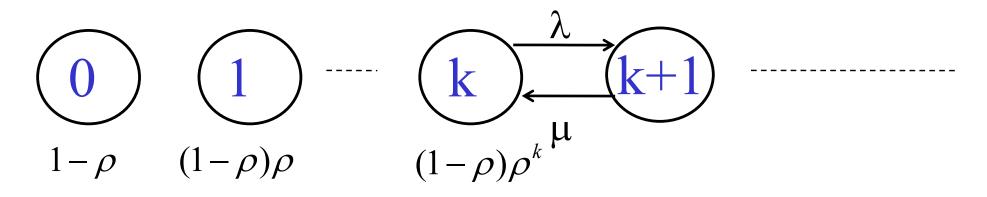

$$p_{k+1} = \frac{\lambda}{\mu} p_k = \left(\frac{\lambda}{\mu}\right)^{k+1} p_0 = \rho^{k+1} p_0$$

$$|p_0 = 1 - \rho|$$

$$\rho = \frac{\lambda}{\mu}$$

Recap: Analysis of Delay

Average queueing delay:

$$\sum_{k=0}^{\infty} p_k \cdot k \cdot \frac{1}{\mu} = \sum_{k=0}^{\infty} \rho^k (1 - \rho) k \frac{1}{\mu}$$

□ Transmission delay:

$$S = \frac{1}{\mu}$$

Queueing + transmission:

Recap: Analysis of Delay

$$\rho = \frac{\lambda}{\mu}$$

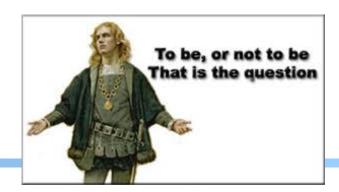

$$S = \frac{1}{\mu}$$

average queueing delay:
$$w = S \frac{\rho}{1 - \rho}$$

queueing + trans =
$$S \frac{\rho}{1-\rho}$$
 + $S = S \frac{1}{1-\rho}$

For a demo of M/M/1, see:

Recap: Statistical Multiplexing

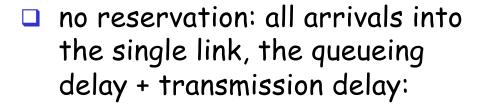

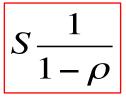

A simple model to compare bandwidth efficiency of

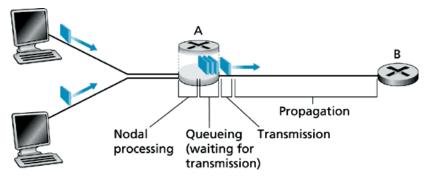

- reservation/dedication (aka circuit-switching) vs
- no reservation (aka packet switching)

setup

- a single bottleneck link with service rate μ
- n flows; each flow has an arrival rate of λ/n

reservation: each flow uses its own reserved (sub)link with rate μ /n, the queueing delay + transmission delay:

For each flow i:
$$\rho_i = \frac{\lambda/n}{\mu/n} = \rho$$

$$S_i = \frac{1}{\mu/n} = nS$$

<u>Summary:</u> <u>Packet Switching vs. Circuit Switching</u>

- Advantages of packet switching over circuit switching
 - most important advantage of packet-switching over circuit switching is statistical multiplexing, and therefore more efficient bandwidth usage
- Disadvantages of packet switching
 - o potential congestion: packet delay and high loss
 - protocols needed for reliable data transfer, congestion control
 - it is possible to guarantee quality of service (QoS) in packet-switched networks and still gain statistical multiplexing, but it adds much complexity
 - packet header overhead
 - per packet processing overhead

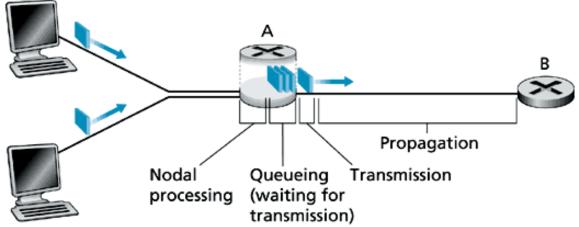

Outline

- Admin. and recap
- > A taxonomy of communication networks
 - o circuit switched networks
 - o packet switched networks
 - o circuit switching vs. packet switching
 - datagram and virtual circuit packet switched networks

A Taxonomy of Packet-Switched Networks According to Routing

Two types of packet switching

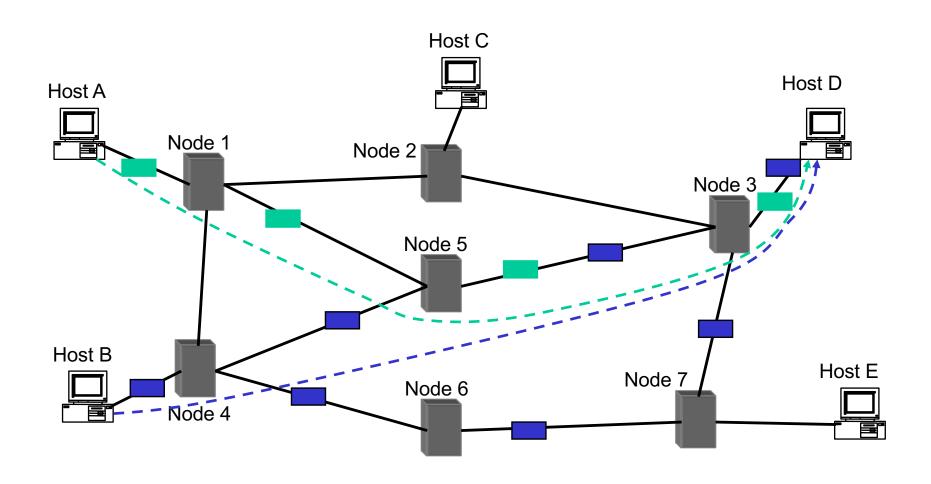

- datagram network
 - each packet of a flow is switched independently
- o virtual circuit network:
 - all packets from one flow are sent along a pre-established path (= virtual circuit)

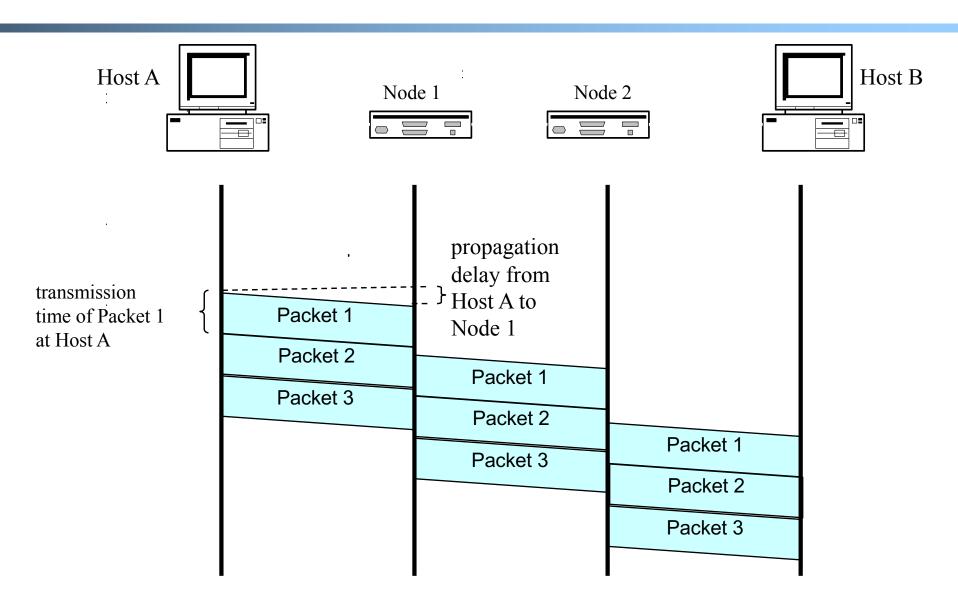

Datagram Packet Switching

- Commonly when we say packet switching we mean datagram switching
- Example: IP networks
- Each packet is independently switched
 - each packet header contains complete destination address
 - receiving a packet, a router looks at the packet's destination address and searches its current routing table to determine the possible next hops, and pick one
- Analogy: postal mail system

Datagram Packet Switching

Timing Diagram of Datagram Switching

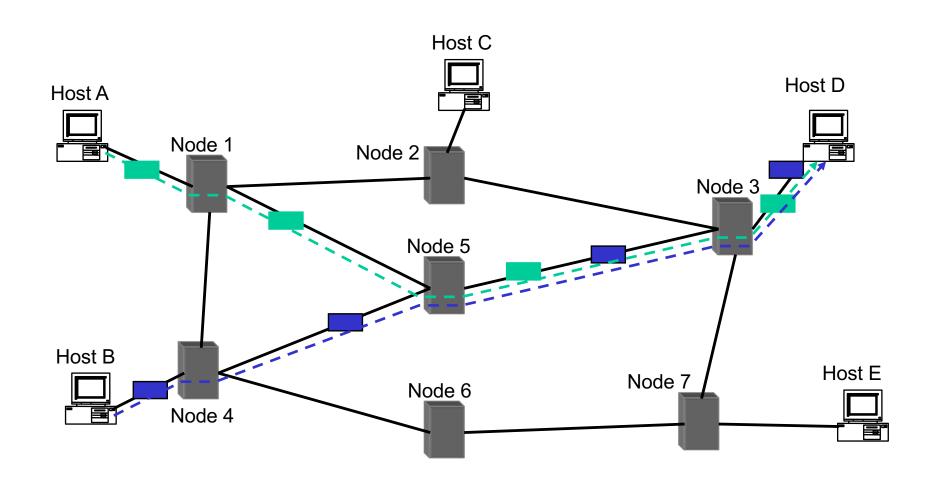

Virtual-Circuit Packet Switching

- Example: Multiple Label Packet Switching (MPLS) in IP networks
- Hybrid of circuit switching and datagram switching
 - fixed path determined at virtual circuit setup time, remains fixed thru flow
 - o Implementation:
 - each packet carries a short local, tag (virtual-circuit (VC) # tag determines next hop

	Incoming VC#	Outgoing Interface	Qo5
	12	2	
<u>;</u>)	; 16	3	
	20	3	

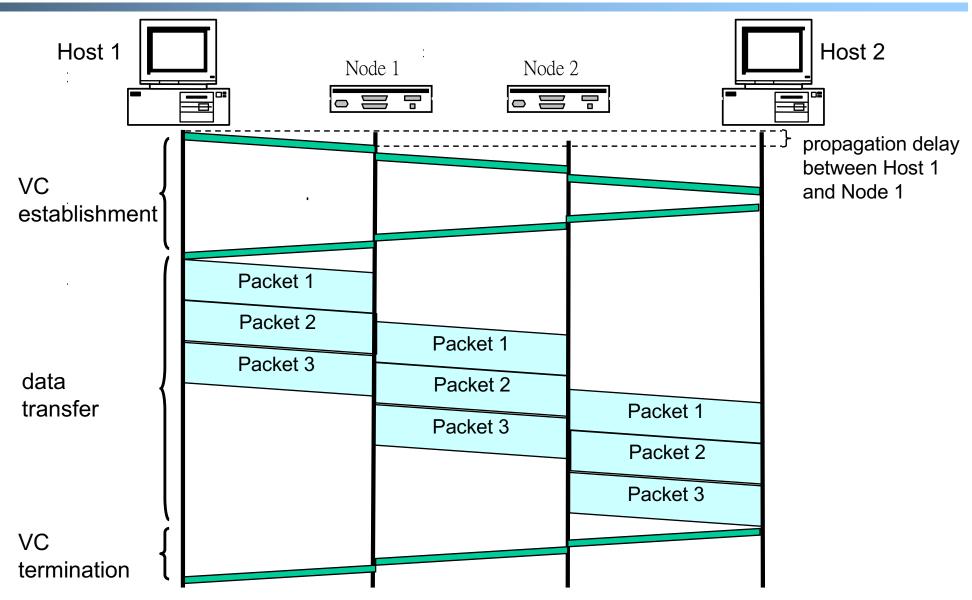

Virtual-Circuit Switching

Virtual-Circuit Packet Switching

- □ Three phases
 - 1. VC establishment
 - 2. Data transfer
 - 3. VC disconnect

Timing Diagram of Virtual-Circuit Switching

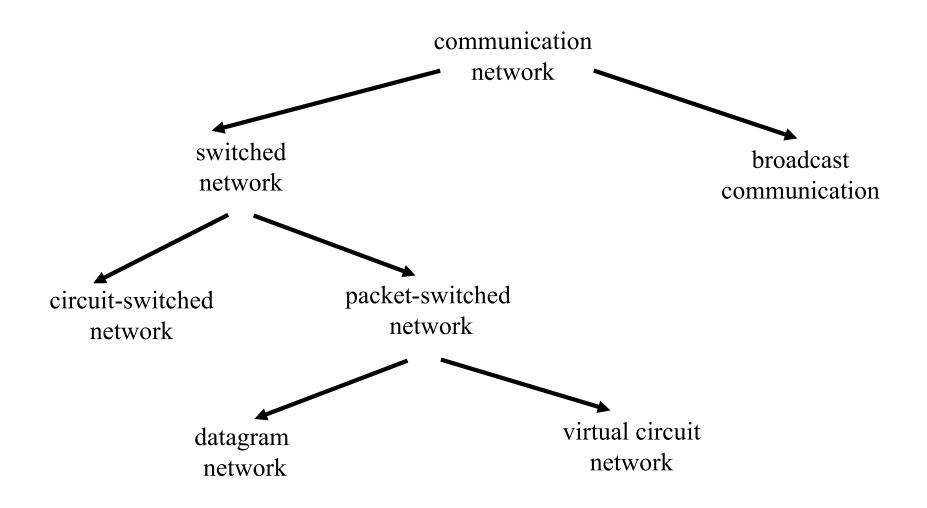

<u>Discussion: Datagram Switching</u> <u>vs. Virtual Circuit Switching</u>

■ What are the benefits of datagram switching over virtual circuit switching?

■ What are the benefits of virtual circuit switching over datagram switching?

Summary of the Taxonomy of Communication Networks

Summary of Progress

■ We have seen the hardware infrastructure, the basic communication scheme, a next key question is how to develop the software system.

Summary of Progress

Outline

- Admin. and recap
- A taxonomy of communication networks
- Layered network architecture
 - > what is layering?
 - why layering?
 - □ how to determine the layers?
 - □ ISO/OSI layering and Internet layering

What is Layering?

■ A technique to organize a networked system into a succession of logically distinct entities, such that the service provided by one entity is solely based on the service provided by the previous (lower level) entity.

Outline

- Admin. and recap
- A taxonomy of communication networks
- □ Layered network architecture
 - what is layering?
 - > why layering?

Why Layering?

Networks are complex!

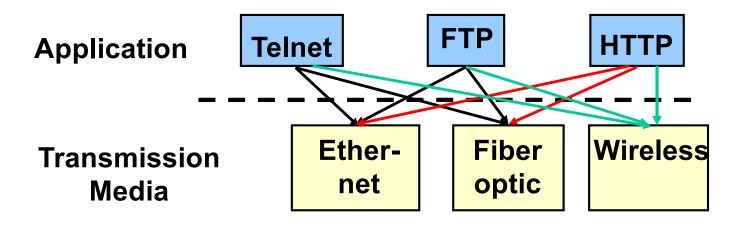

- many "pieces":
 - hardware
 - hosts
 - routers
 - links of various media
 - software
 - applications
 - · infrastructure

- Dealing with complex systems:
 explicit structure allows
 identification of the relationship
 among a complex system's pieces
 - layered reference model for discussion

Modularization eases maintenance, updating of system:

 change of implementation of a layer's service transparent to rest of system, e.g., changes in routing protocol doesn't affect rest of system

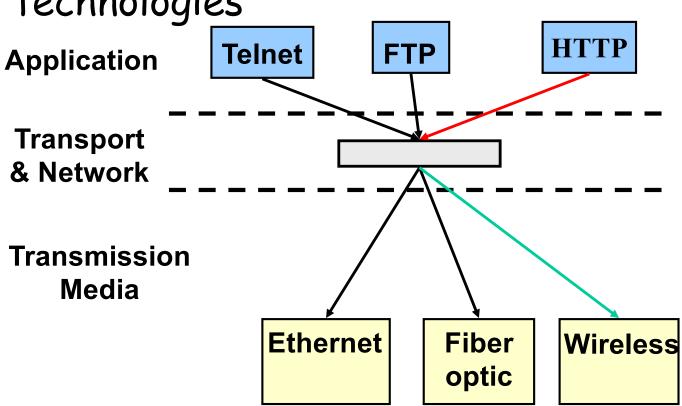

An Example: No Layering

No layering: each new application has to be re-implemented for every network technology!

An Example: Benefit of Layering

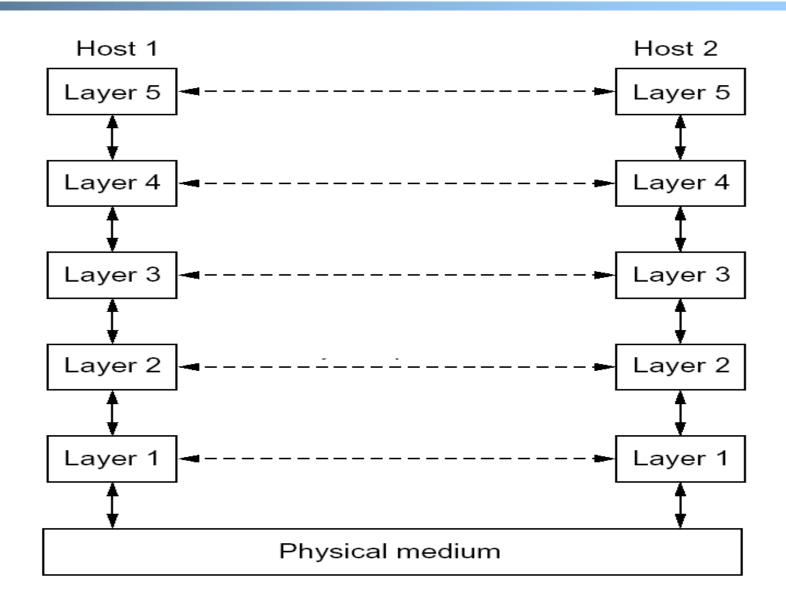

□ Introducing an intermediate layer provides a common abstraction for network technologies

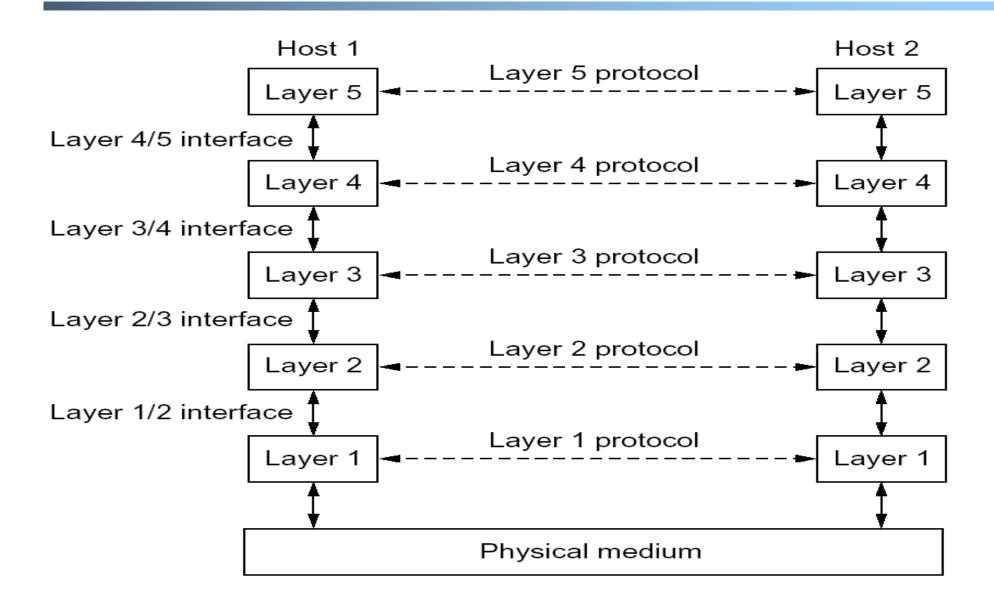

ISO/OSI Concepts

- □ ISO International Standard Organization
- OSI Open System Interconnection
- Service says what a layer does
- □ Interface says how to access the service
- Protocol specifies how the service is implemented
 - a set of rules and formats that govern the communications between two or more peers

An Example of Layering

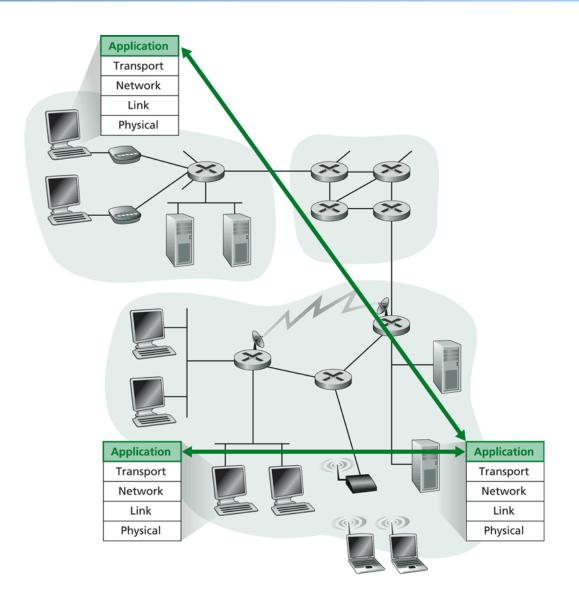

An Example of Layering

<u>Layering -> Logical Communication</u>

E.g.: application

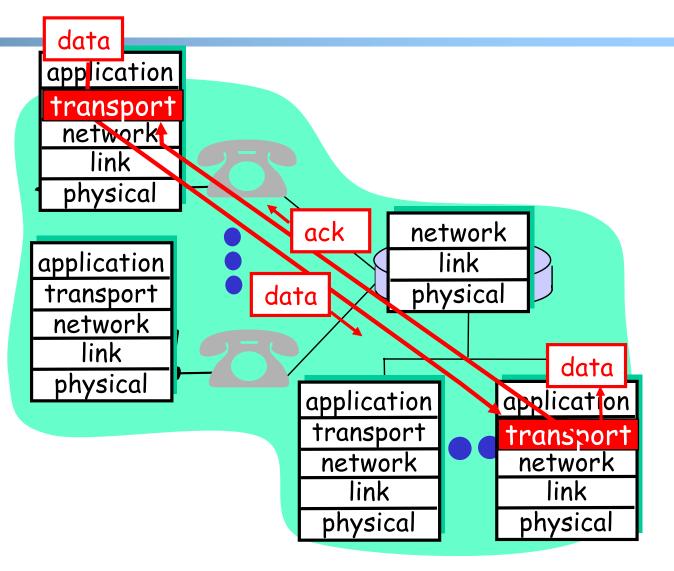

- provide services to users
- application protocol:
 - send messages to peer
 - for example, HELO, MAIL FROM, RCPT TO are messages between two SMTP peers

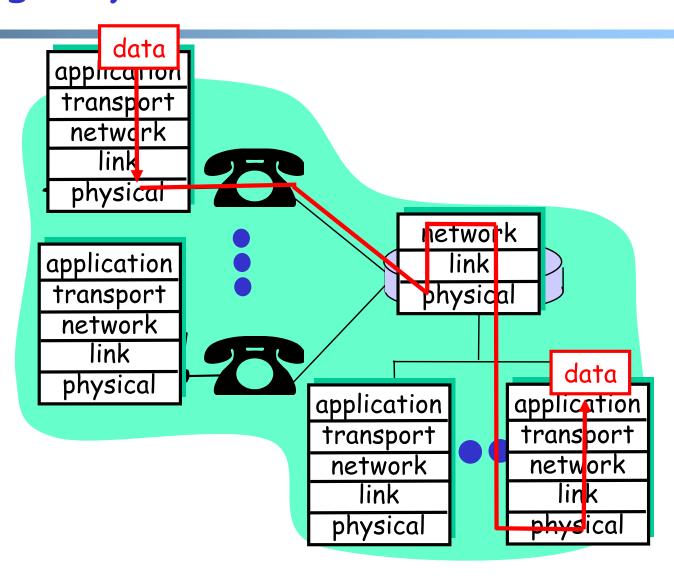

Layering: Logical Communication

E.g.: transport

- Trans. msg for app
- Transport protocol
 - add control info to form "segment"
 - send segment to peer
 - wait for peer to ack receipt; if no ack, retransmit

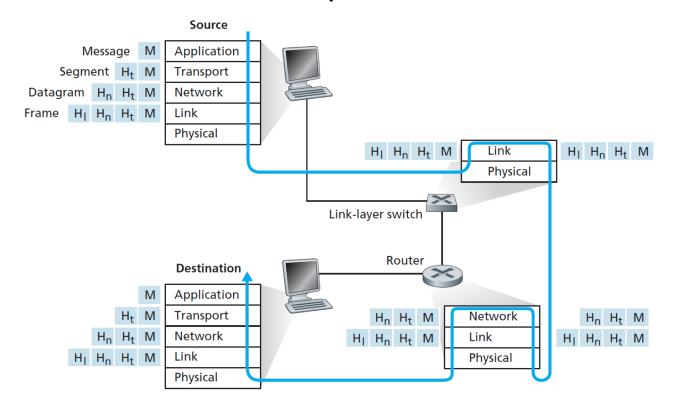

Layering: Physical Communication

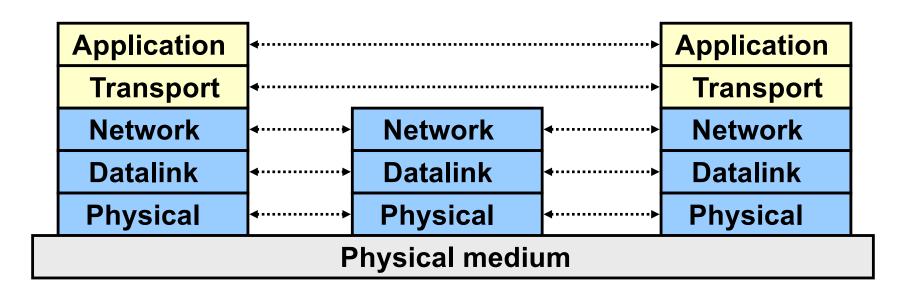

Protocol Layering and Meta Data

Each layer takes data from above

- adds header (meta) information to its peer to create new data unit
- passes new data unit to layer below

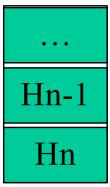

<u>Packet as a Stack in a Layered</u> <u>Architecture</u>

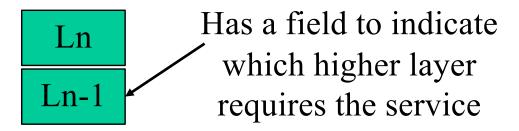

Some Implications of Layered Architecture

A packet as a stack container

■ Each layer needs multiplexing and demultiplexing to serve layer above

Key design issue:

How do you divide functionalities among the layers?

Outline

- Admin. and recap
- A taxonomy of communication networks
- Layered network architecture
 - what is layering?
 - why layering?
 - > how to determine the layers?

The End-to-End Arguments

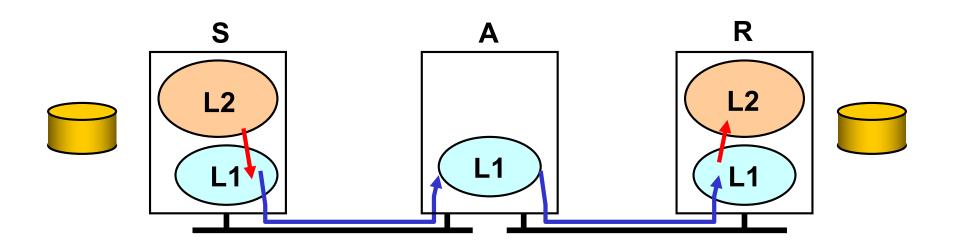

The function in question can completely and correctly be implemented only with the knowledge and help of the application standing at the endpoints of the communication systems. Therefore, providing that questioned function as a feature of the communications systems itself is not possible.

J. Saltzer, D. Reed, and D. Clark, 1984

What does the End-to-End Arguments Mean?

- □ The application knows the requirements best, place functionalities as high in the layer as possible
- □ Think twice before implementing a functionality at a lower layer, even when you believe it will be useful to an application

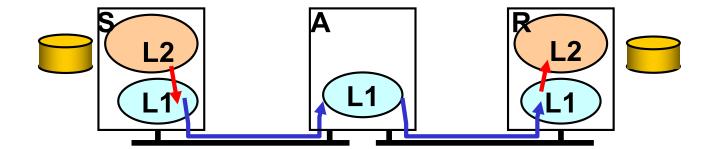

Example: Where to Provide Reliability?

- □ Solution 1: the network (lower layer L1) provides reliability, i.e., each hop provides reliability
- Solution 2: the end host (higher layer L2) provides reliability, i.e., end-to-end check and retry

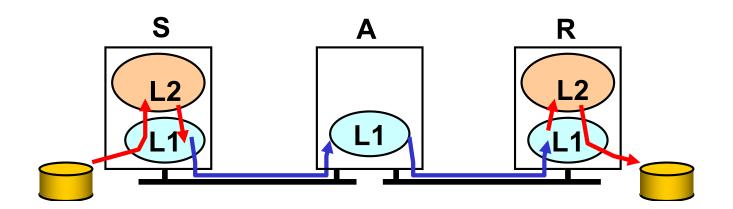

What are Reasons for Implementing Reliability at Higher Layer?

- The lower layer cannot completely provide the functionality
 - the receiver has to do the check anyway!
- Implementing it at lower layer increases complexity, cost and overhead at lower layer
 - shared by all upper layer applications → everyone pays for it, even if you do not need it
- The upper layer
 - knows the requirements better and thus may choose a better approach to implement it

Are There Reasons Implementing Reliability at Lower Layer?

- □ Improve performance, e.g., if high cost/delay/... on a local link
 - o improves efficiency
 - o reduces delay
- □ Share common code, e.g., reliability is required by multiple applications

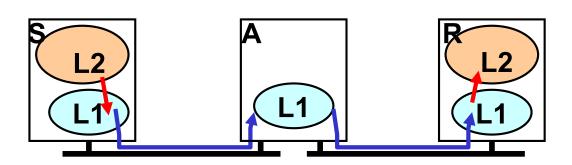

Summary: End-to-End Arguments

- □ If a higher layer can do it, don't do it at a lower layer -- the higher the layer, the more it knows about the best what it needs
- Add functionality in lower layers iff it
 - (1) is used by and improves performance of a large number of (current and potential future) applications,
 - (2) does not hurt (too much) other applications, and
 - (3) does not increase (too much) complexity/overhead
- Practical tradeoff, e.g.,
 - allow multiple interfaces at a lower layer (one provides the function; one does not)

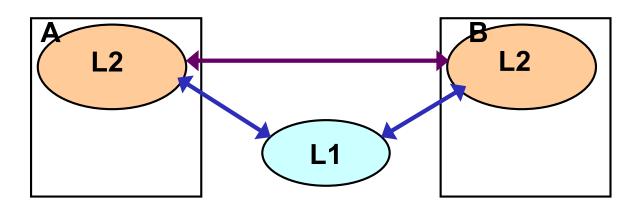

Examples

- We used reliability as an example
- Assume two layers (L1: network; L2: end-to-end).
 Where may you implement the following functions?
 - security (privacy of traffic)
 - quality of service (e.g., delay/bandwidth guarantee)
 - congestion control (e.g., not to overwhelm network links or receiver)

Example

- □ Consider the presence service in a social networking system: shows which contacts are online (e.g., skype)
 - implementing by end user's host app or through a third party service?

Challenges

Challenges to build a good (networking) system: find the right balance between:

end-to-end arguments

reuse, interoperability, implementation effort (apply layering concepts)

No universal answer: the answer depends on the goals and assumptions!

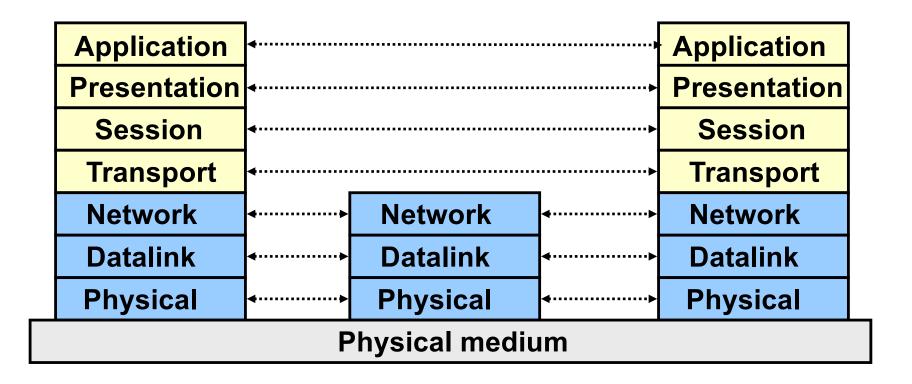

<u>Discussion: Limitations of</u> <u>Layered Architecture</u>

Outline

- Admin. and recap
- A taxonomy of communication networks
- Layered network architecture
 - □ what is layering?
 - ■why layering?
 - □how to determine the layers?
 - > ISO/OSI layering and Internet layering

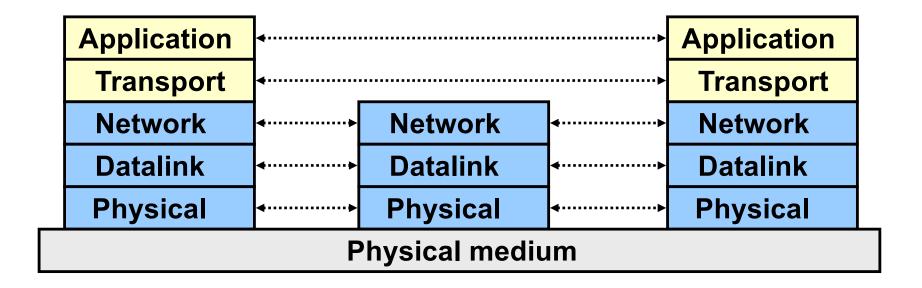

ISO/OSI Reference Model

- Seven layers
 - highest four layers are implemented in host

Internet Layering

- Five layers
 - highest two layers are implemented in host

Internet Protocol Layers

Five layers

- Application: applications
 - ftp, smtp, http, p2p, IP telephony, blockchain, MapReduce, ...
- Transport: host-host data transfer
 - tcp (reliable), udp (not reliable)
- Network: routing of datagram from source to destination
 - ipv4, ipv6
- Link: data transfer between neighboring network elements
 - ethernet, 802.11, cable, DSL, ...
- Physical: bits "on the wire"
 - · cable, wireless, optical fiber
